

## FAQ

### What is AZRAS?

AZRAS is an "Adaptive Zero-Rebuild Asset System." By separating a long-life RC structural core from independently renewable timber infill, it is an architectural platform that allows a building's asset value to be maintained and updated without demolition or full reconstruction.

### Is AZRAS a construction method?

No.

AZRAS is not simply a construction method — it is an asset-oriented design philosophy and an architectural platform.

### Is it patented?

Yes, it is patented. The technology is based on a patent filed in 2004 and published in 2005 (Japanese Patent Application No. 2005-240511).

### Can it be adapted to local building codes?

Yes.

It can be introduced by adjusting the structural form (e.g., wall-type structure, moment-frame structure) according to the building codes of each country or region.

### How does it differ from conventional Skeleton-Infill (SI) systems?

| Item                                 | Conventional SI | AZRAS      |
|--------------------------------------|-----------------|------------|
| Interior layout changes              | Possible        | Possible   |
| Complete façade renewal              | Limited         | Fully free |
| 2nd-floor spatial reconfiguration    | Not possible    | Possible   |
| Staircase / void repositioning       | Not possible    | Possible   |
| Full-scale seismic verification      | Rare            | Completed  |
| Initial cost (vs. light-gauge steel) | Higher          | Equivalent |

### Is AI required?

No.

The use of AI is optional. AZRAS has strong compatibility with AI-era technologies such as robotic construction and digital twins, but it functions as a building system without AI as well.

**Can existing buildings adopt AZRAS?**

It is possible in some cases. Applicability depends on the existing building's structural type and degree of deterioration, so an individual structural survey is required.
